Reproducible Research: Peer Assessment 1

Created Sun Oct 19 18:29:54 2014

Loading and preprocessing the data

Load all required libraries

```
library(data.table)
library(lattice)
```

Create **data** folder in your workspace (if there is no such folder), download the original zip file and store it in the **data** folder.

```
if (!file.exists("data")){
          dir.create("data")
}
fileUrl <- "https://d396qusza40orc.cloudfront.net/repdata%2Fdata%2Factivity.zip"
if (!file.exists("./data/activity.zip")){
          download.file(fileUrl, destfile = "./data/activity.zip", method = "curl")
}</pre>
```

Read data from the zip file and store it as a data table activity

```
activity <- read.csv(unz("./data/activity.zip", "activity.csv"), header = TRUE)
activity <- as.data.table(activity)
activity$date <- as.Date(activity$date)
activity$steps <- as.numeric(activity$steps)
summary(activity)</pre>
```

```

## NA's
          :2304
```

What is mean total number of steps taken per day?

As one can see, all NA values in the dataset belong to the steps variable. What is more interesting, the following property holds: For any date, the variable steps has at least one missing value if and only if all its values for that day are missing. There are exactly 8 such days in the dataset. Let's call such days NA days.

One can have a look at

```
split(activity$steps, activity$date)
```

to check that our data set has the property above.

It is probably better to completely exclude NA days from computations, rather than have 8 artificial days with 0 total steps. (The total number of steps for NA days would be 0 since after removing all missing values, such days would contain no observations, and the sum of elements of empty vector is 0). Therefore, it make sense to first calculate the total number of steps for each day and only after that remove missing values.

Let's calculate the total number of steps taken each day:

```
total <- activity[, list(totalSteps = sum(steps)), by = date]
summary(total)</pre>
```

```

As you can see, we have the same summary after we remove missing values

Make a histogram of the total number of steps taken each day

Total number of steps per day

For comparison, let's remove missing values while computing

```
total0 <- activity[, list(totalSteps = sum(steps, na.rm = TRUE)), by = date]</pre>
```

Look at the summary. The min value is now 0, which clearly affects the mean and median

summary(total0)

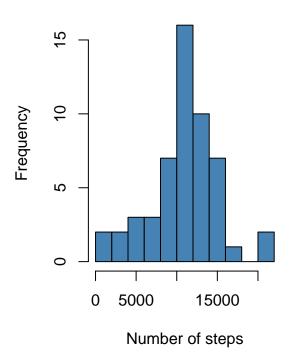

```
##

```

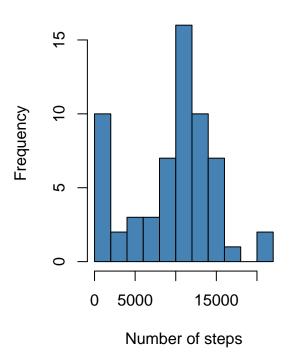

Now compare the plots: the right one has eight more 0-days

```
par(mfrow = c(1, 2))
hist(total$totalSteps, col = "steelblue",
    main = "Total number of steps per day \n(without NA days)",
    xlab = "Number of steps", breaks = 12)
hist(totalO$totalSteps, col = "steelblue",
    main = "Total number of steps per day \n(with NA days)",
    xlab = "Number of steps", breaks = 12)
```

Total number of steps per day (with NA days)

par(mfrow = c(1, 1))

Find the mean and median total number of steps taken per day. Actually, we have already know them from the summary, yet let's compute them again

mean(total\$totalSteps)

[1] 10766.19

median(total\$totalSteps)

[1] 10765

Again, see the difference if keep NA days in the dataset

mean(total0\$totalSteps)

[1] 9354.23

median(total0\$totalSteps)

[1] 10395

What is the average daily activity pattern?

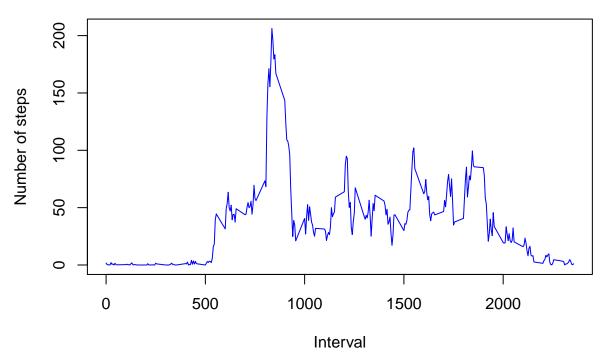

Find average number of steps taken per interval (across all days of the experiment). Here missing values are distributed across all intervals. Therefore, we remove them from the data set during the calculations

```
average <- activity[, list(meanSteps = mean(steps, na.rm = TRUE)), by = interval]
head(average)</pre>
```

```
## interval meanSteps
## 1: 0 1.7169811
## 2: 5 0.3396226
## 3: 10 0.1320755
## 4: 15 0.1509434
## 5: 20 0.0754717
## 6: 25 2.0943396
```

Make a time series plot of the 5-minute interval (x-axis) and the average number of steps taken, averaged across all days (y-axis)

Averge number of steps taken per interval

Which 5-minute interval, on average across all the days in the dataset, contains the maximum number of steps?

```
which.max(average$meanStep)
```

```
## [1] 104
```

```
average$interval[which.max(average$meanStep)]
```

```
## [1] 835
```

Calculate the total value of missing values in the data set. We already know that from the summary. Nevertheless, let's calculate it again. As we know, all missing values are in the steps variable:

```
length(which(is.na(activity$steps)))
```

```
## [1] 2304
```

Imputing missing values

We know that if steps observations for any day contain at lest one missing value, they consist of missing values only. Therefore, the strategy "use the mean/median for that day" won't work. Let's use the strategy "the mean for that 5-minute interval" to impute missing values.

Using data.table package, set key interval to both the original activity data set and the date average that stores the mean total number of steps per interval. Merge the data tables and replace missing values of the variable steps with average values from the meanSteps. However, first we create a new copy of the activity data table.

```
activity1 <- copy(activity)
setkey(activity1, interval)
setkey(average, interval)
activity1 <- merge(activity1, average)
activity1[is.na(steps), steps := meanSteps]
activity1[, meanSteps := NULL]</pre>
```

summary(activity1)

```

## 7:
             0 1.716981 2012-10-08
## 8:
```

As you can see, all missing values have disappeared.

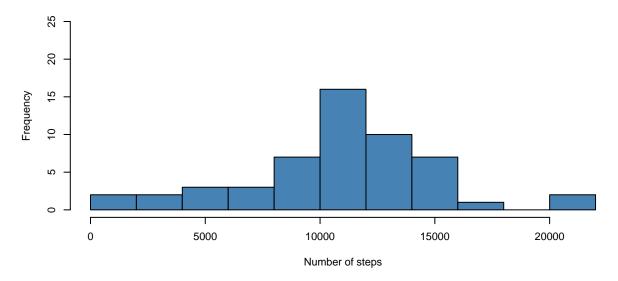

Calculate the total number of steps taken each day

```
total1 <- activity1[, list(totalSteps = sum(steps)), by = date]</pre>
```

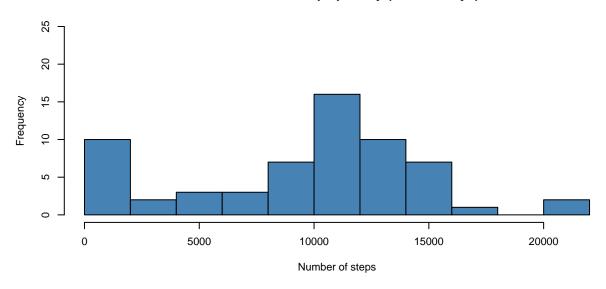

Make a histogram of the total number of steps taken each day. Below are comparison plots. Old data is without $NA\ days$

```
par(mfrow = c(3, 1))
hist(total$totalSteps, col = "steelblue",
    main = "Total number of steps per day (without NA days)",
    xlab = "Number of steps", breaks = 12, ylim = c(0,25))
hist(total0$totalSteps, col = "steelblue",
    main = "Total number of steps per day (with NA days)",
    xlab = "Number of steps", breaks = 12, ylim = c(0,25))
hist(total1$totalSteps, col = "steelblue",
    main = "Total number of steps per day (imputed NA values)",
    xlab = "Number of steps", breaks = 12, ylim = c(0,25))
```

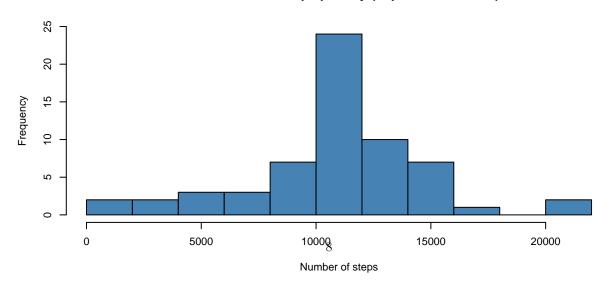

Total number of steps per day (without NA days)

Total number of steps per day (with NA days)

Total number of steps per day (imputed NA values)

```
par(mfrow = c(1, 1))
```

From the graph one can see that after we imputed missing values with estimates, 8 artificial 0-steps days have transformed into "post popular" days with approximately 11k steps.

Find again the mean and median total number of steps taken per day

```
mean(total1$totalSteps)
```

[1] 10766.19

median(total1\$totalSteps)

[1] 10766.19

and compare them with the old values.

The old values obtained from the data set without NA days

mean(total\$totalSteps)

[1] 10766.19

median(total\$totalSteps)

[1] 10765

Result: Clearly, and as one could expect, our initial strategy with removing *NA days* from the data set gave us essentially the same results as the strategy that replaces each missing value with the mean value of steps for a corresponding interval.

The old values obtained from the data set that includes NA days

mean(total0\$totalSteps)

[1] 9354.23

median(total0\$totalSteps)

[1] 10395

Result: If we compare results obtained from the new data set and the original one that includes NA days, the difference is pretty significant. Clearly, once we replace NAs with estimates and run our analysis, we won't get 0 total steps for 8 NA days. Instead, we will get some positive values calculated from the estimates. As a result, both the **mean** and **median** total number of steps per day have increased.

Are there differences in activity patterns between weekdays and weekends?

Create a new factor variable in the dataset with two levels – "weekday" and "weekend" indicating whether a given date is a weekday or weekend day.

```
activity1[weekdays(date) %in% c("Saturday", "Sunday"), day := "weekend"]
head(activity1, 8)
##
